

# Property25 — team deploy manual

How to ship code from your laptop to GitHub, the API, and the live app the team uses.

| What                  | URL                                                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| Live app (share this) | <a href="https://midpointblue.co.za/real/#!/login">https://midpointblue.co.za/real/#!/login</a>                           |
| API                   | <a href="https://property25.onrender.com">https://property25.onrender.com</a>                                             |
| Repo                  | <a href="https://github.com/untitledproject223-lang/Property25">https://github.com/untitledproject223-lang/Property25</a> |

## Mental model (read this once)

There are **two** production pieces. They do **not** update the same way.

Your laptop

| Piece       | Host            | Updates when...                                         |
|-------------|-----------------|---------------------------------------------------------|
| Backend API | Render          | You merge/push to main (auto)                           |
| Frontend UI | Midpoint cPanel | Someone <b>rebuilds</b> and <b>FTP uploads</b> website/ |

**cPanel does not pull from GitHub.** Pushing a branch alone will **not** change <https://midpointblue.co.za/real/> until the FTP step runs.

Do **not** deploy this product to Azure.

## 1. Day-to-day: work on a branch

```
git checkout main
git pull origin main
git checkout -b feature/short-description
```

Make your changes, then:

```
git add .
git status          # never commit .env, server/.env, passwords, FTP scripts
git commit -m "Describe why this change exists."
git push -u origin HEAD
```

Open a PR into main on GitHub. After review/merge:

```
git checkout main
git pull origin main
```

**API:** Render rebuilds from main automatically (usually a few minutes). **Frontend:** still needs the cPanel steps below if UI files changed.

## 2. Local setup (once per machine)

```
git clone https://github.com/untitledproject223-lang/Property25.git
cd Property25
npm install
cd server && npm install && cd ..
```

Create server/.env from server/.env.example (ask the team lead for Neon + JWT values).

Frontend against the **live API** when testing production behaviour:

```
# project root – .env.production (already used by production builds)
VITE_API_URL=https://property25.onrender.com
```

Dev against local API:

```
# optional .env.local
VITE_API_URL=http://localhost:4000

npm run dev:api    # terminal 1 – API
npm run dev        # terminal 2 – UI
```

---

## 3. Push the live Midpoint UI (cPanel)

Do this after UI changes are on main (or from the branch you intend to ship — usually main).

### 3.1 Build

From the **repo root**:

```
git checkout main
git pull origin main
```

```
# Confirm production API URL exists:
# .env.production → VITE_API_URL=https://property25.onrender.com
```

```
npm run build:website
```

That writes a static site into website/:

- website/index.html
- website/assets/\* (js, css, wasm)
- website/.htaccess

Vite is configured with base: ' /real/' so paths match Midpoint.

### 3.2 Upload to cPanel (FTP)

| Setting       | Value                                             |
|---------------|---------------------------------------------------|
| Host          | midpointblue.co.za                                |
| Port          | 21 (FTP, passive mode)                            |
| User          | property25deploy@midpointblue.co.za               |
| Password      | Ask the team lead (do <b>not</b> commit it)       |
| Remote folder | FTP account home = public_html/real (upload to /) |

Upload **everything inside** website/ (overwrite existing files):

- index.html
- .htaccess
- assets/ (all files)

**GUI:** FileZilla / WinSCP — connect with the table above, drag website/ contents into the remote root.

**CLI (PowerShell + Python):** ask the lead for a one-off upload script, or set env vars and run a local helper that is **not** committed:

```
$env:FTP_HOST = "midpointblue.co.za"
$env:FTP_USER = "property25deploy@midpointblue.co.za"
$env:FTP_PASS = "<ask-lead>" # never commit this
# then run your local ftp_upload.py that reads those env vars
```

### 3.3 Verify

- 1 Hard-refresh: <https://midpointblue.co.za/real/#/login> (Ctrl+Shift+R)
- 2 View page source — `index.html` should reference the **new** hashed files under `/real/assets/...`
- 3 Log in and smoke-test the screens you changed
- 4 If login fails but the page loads, check Render: <https://property25.onrender.com/api/health>

## 4. Who does what

| Change type               | Git       | Render (API) | Midpoint FTP    |
|---------------------------|-----------|--------------|-----------------|
| Backend only (server/...) | PR → main | Auto         | Not needed      |
| Frontend only (src/...)   | PR → main | Usually none | <b>Required</b> |
| Both                      | PR → main | Auto         | <b>Required</b> |

Prefer one person (or a short rotation) to own the Midpoint FTP step so credentials stay controlled.

## 5. Checklist before you share with the team

- ☐ PR merged to main (or you built from the commit you mean to ship)
- ☐ Render deploy finished green (API changes)
- ☐ `npm run build:website` succeeded with `VITE_API_URL=https://property25.onrender.com`
- ☐ FTP upload of full website/ completed
- ☐ Hard-refresh on <https://midpointblue.co.za/real/#/login> works
- ☐ No secrets committed (`.env`, FTP password, Neon URL)

## 6. Common mistakes

| Mistake                                    | Result                                   |
|--------------------------------------------|------------------------------------------|
| Push branch, skip FTP                      | Midpoint still shows old UI              |
| Build without <code>.env.production</code> | UI may point at wrong/missing API        |
| Upload only <code>index.html</code>        | Broken site (missing hashed JS/CSS/wasm) |
| Commit FTP password or <code>.env</code>   | Security incident — rotate secrets       |
| Deploy to Azure                            | Out of scope — Midpoint + Render only    |

## 7. Quick “ship it” card

```
# 1) Merge your PR to main, then:
git checkout main && git pull origin main

# 2) API is already deploying on Render if server/ changed.

# 3) Ship UI to Midpoint:
npm run build:website
# 4) FTP contents of website/ → property25deploy@midpointblue.co.za (remote /)

# 5) Share:
# https://midpointblue.co.za/real/#/login
```
